

# Algorithmic Methods of Data Mining

## Homework 4

Davide Aureli, Michela Bragagnolo, Dastagiri Dudekula

December 18, 2017

## POINT 1

In this point we have to create a graph  $G$ , whose nodes are the authors and they are connected with weighted edges if they share at least one publication. On the full dataset we obtained a disconnected graph with 904664 nodes and 3679242 edges.

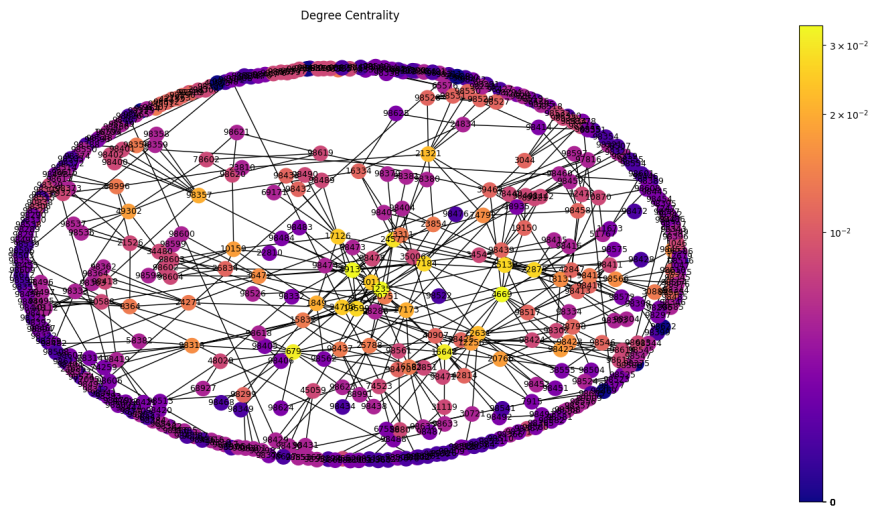

## POINT 2

### 2.A

Given a conference in input, we need to return the subgraph induced by the set of authors who published at the input conference at least once. After obtaining the subgraph we can calculate some centrality measures, which give us relative measures of importance in the network.

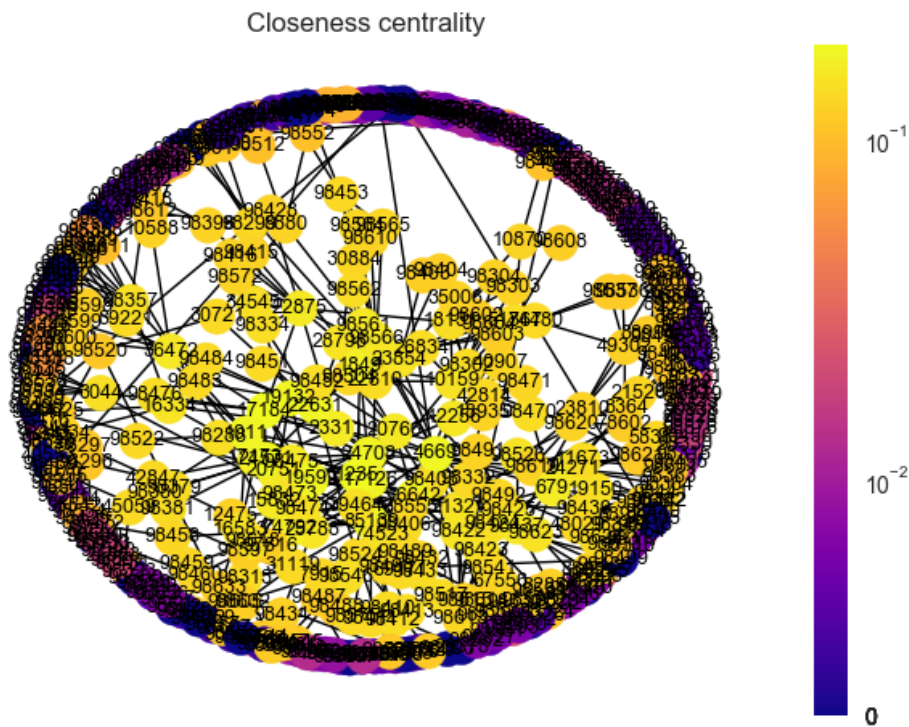

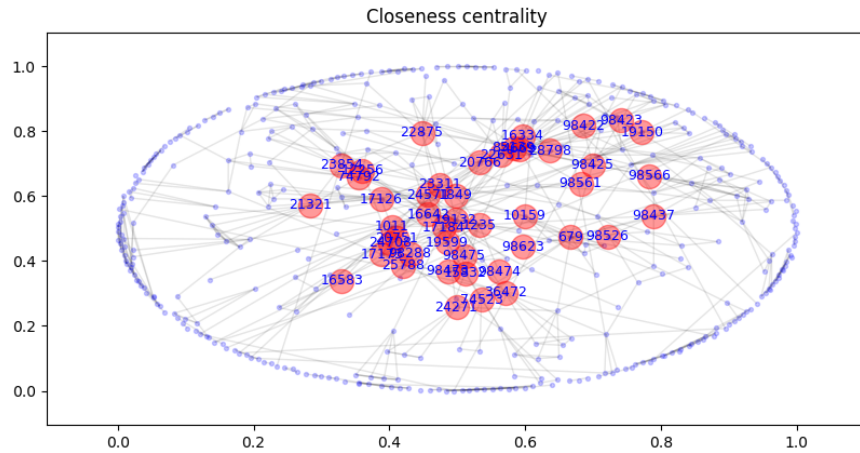

To show the results of these measures we used as example in input the conference 'conf/iitsi/2010'. Associated to this conference we obtained a disconnected subgraph with 447 nodes and 726 edges.

The first measure we consider is the *degree centrality*; the intuition is that nodes with more connections are more influential and important in a network. The highlighted nodes in the next graph corresponds to the most relevant authors.

On the second figure we can identify better the main authors, such as: Ying Wang (id:1235), Wei Li (id:19132) and Hui Li (id:4669).

The *closeness centrality* is a measure where each node's importance is determined by closeness to all other nodes.

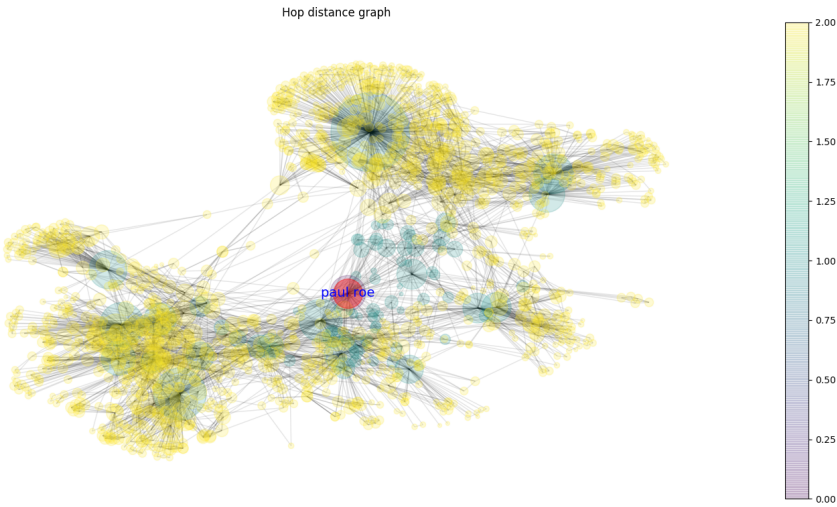

As we can see on the figures, all the most important nodes, with high closeness are centered in the middle of the graph.

The last measure is the *betweenness centrality*, where vertices with high betweenness may have considerable influence within a network by virtue of their control over information passing between others. They are also the ones whose removal from the network will most disrupt communications between other vertices because they lie on the largest number of paths.

The most influent nodes are situated approximately in the middle, where there are more connections, as we can notice with the huge contrast in the color of the nodes. The most important author seems to be Hui Li with id 4669 in that case.

For example, if we want to see the connection of the author Paul Roe until level 2, we obtained the following plot.

The red node highlighted is our author and the other nodes are colored based on their distance, at distance 1 we have green nodes and at distance 2 we have yellow nodes. Also the shape of the nodes reflect the number of connections of each node.
